Căutare avansată

- ❑ Căutarea avansată se accesează din „Article lookup” / „More search options” 1.
- ❑ Motorul de căutare avansată permite căutarea de documente, în funcție de diferite criterii. Pentru început, se vor completa câmpurile destinate cuvintelor-cheie, se vor crea legături între ele prin operatori logici, iar apoi se va selecta unul dintre criteriile după care se va face căutarea. Pentru a rafina căutarea, se va selecta și intervalul temporal 3, subiectul 4 sau revista 5 (din care să se efectueze căutarea).

The screenshot displays the IOPscience search interface. On the left, the 'Find article' section shows a search for '2D Mater. (2014 - present)' with fields for 'Volume', 'Issue', and 'Article or page'. A 'More search options' link is highlighted with a callout '1'. The main 'Search' section includes a search bar, a dropdown menu for search criteria (with 'Title/Abstract' selected and callout '2'), a date range selector (with callout '3'), and a 'Search now' button. Below the search bar, there are two columns of filters: 'Subjects' (with callout '4') and 'Journals' (with callout '5'). The 'Subjects' list includes categories like 'Accelerators, beams and electromagnetism' and 'Astrophysics and astroparticles'. The 'Journals' list includes titles like 'Journal of Physics A: General Physics (1968-1972)' and 'Journal of Physics B: Atomic and Molecular Physics (1968-1987)'. On the right, a 'PACS/MSC search' section is visible, showing '0 IOPscience result(s)' and a search box for PACS/MSC codes.

Abstract

In solar cell technology, the current trend is to thin down the active absorber layer. The main advantage of a thinner absorber is primarily the reduced consumption of material and energy during production. For thin film silicon (Si) technology, thinning down the absorber layer is of particular interest since both the device throughput of vacuum deposition systems and the stability of the devices are significantly enhanced. These features lead to lower cost per installed watt peak for solar cells, provided that the (stabilized) efficiency is the same as for thicker devices. However, merely thinning down inevitably leads to a reduced light absorption. Therefore, advanced light trapping schemes are crucial to increase the light path length. The use of elongated nanostructures is a promising method for advanced light trapping. The enhanced optical performance originates from orthogonalization of the light's travel path with respect to the direction of carrier collection due to the radial junction, an improved anti-reflection effect thanks to the three-dimensional geometric configuration and the multiple scattering between individual nanostructures. These advantages potentially allow for high efficiency at a significantly reduced quantity and even at a reduced material quality, of the semiconductor material. In this article, several types of elongated nanostructures with the high potential to improve the device performance are reviewed. First, we briefly introduce the conventional solar cells with emphasis on thin film technology, following the most commonly used fabrication techniques for creating nanostructures with a high aspect ratio. Subsequently, several representative applications of elongated nanostructures, such as Si nanowires in realistic photovoltaic (PV) devices, are reviewed. Finally, the scientific challenges and an outlook for nanostructured PV devices are presented.

1. Introduction

With the explosive growth of world energy demand and the inevitable depletion of fossil fuels, it is becoming more urgent to explore renewable energy resources to reduce the strong reliance of society on primary power generated by fossil fuels, such as oil, coal and natural gas. Solar energy, wind energy, geothermal energy, etc are the most attractive renewable candidates. Among them solar energy is
